COHERENT PRINCIPLE OF ACCELERATION OF CHARGED PARTICLES

V. I. VEKSLER

Electrophysical Laboratory, Academy of Sciences, Moscow

This paper will include a very brief description of a new principle regarding the acceleration of charged particles.

In all existing accelerators of charged particles, the constant and varying electric field accelerating them is created by a powerful external source, and hence the strength of the field is independent, in the first approximation, of the number of particles which are being accelerated.

In resonance accelerators, the electromagnetic field has to be synchronized with the movement of the particles (this is of particular importance in linear accelerators). Finally, none of the existing methods permits the acceleration of neutral bunches of particles.

A new principle of particle acceleration is set forth below. Its distinctive feature lies in the fact that the particle-accelerating electric field is produced by the interaction of a geometrically small group of accelerated particles with another group of charges, plasma or an electromagnetic wave. This method has a number of important features. It appears, in the first place, that the magnitude of the accelerating field produced by this interaction and acting on each particle depends on the

Theoretical studies of various aspects of the coherent acceleration method have been made by M. S. Rabinovich, A. A. Kolomenski, B. M. Bolotovski, L. V. Kovrzhnikh and I. V. Iankov, as well as by A. I. Akhiezer, Ia. Fainberg and their collaborators. The calculations made by these theoretical workers shed light on a number of complicated problems connected with the development of the different variants of this new acceleration principle, and it therefore seems appropriate to describe the new method despite the fact that a great many problems involved still await solution.

1. *Acceleration of charged bunches by means of the medium*

It was pointed out in a paper by Tamm that the loss of energy by particles due to Cerenkov radiation could be reversed, i.e. the medium travelling at a great velocity past charged particles should be able to convey energy to the latter. Up to now, however, no attention has been paid to the possibility of developing an acceleration process of this kind by using a high density electron beam (plasma) as the moving medium. Of course, if a single charge e is

Collective ion acceleration by a reflexing electron beam: Model and scaling

F. Mako

Naval Research Laboratory, Washington, D. C. 20375

T. Tajima

Institute for Fusion Studies, University of Texas, Austin, Texas 78712

(Received 21 June 1983; accepted 2 April 1984)

Analytical and numerical calculations are presented for a reflexing electron beam type of collective ion accelerator. These results are then compared to those obtained through experiment. By constraining one free parameter to experimental conditions, the self-similar solution of the ion energy distribution agrees closely with the experimental distribution. Hence the reflexing beam model appears to be a valid model for explaining the experimental data. Simulation shows in addition to the agreement with the experimental ion distribution that synchronization between accelerated ions and electric field is phase unstable. This instability seems to further restrict the maximum ion energy to several times the electron energy.

I. INTRODUCTION

Experiments on collectively accelerating ions utilizing a reflexing intense relativistic electron beam in a plasma have been carried out.^{1,2} These experiments began to reveal sever-

chronous fashion. Thus, energetic ions would be expected. The ion energy would, of course, be bounded above by the ion to electron mass ratio times the initial electron energy; that is, the energy is bounded when the ions reach the initial

Collective acceleration suggested:

Veksler (1956)

$(\text{ion energy}) \sim (\text{M}/\text{m})(\text{electron energy})$

Many experimental attempts (~'70s):

led to no such amplification

$(\text{ion energy}) \sim (\text{several})x(\text{electron})$

Mako-Tajima analysis (1978;1984)

sudden acceleration, ions untrapped,
electrons return, while some run away
→ #1 gradual acceleration necessary

→ #2 electron acceleration possible
with trapping (with Tajima-
Dawson field), more tolerant for
sudden process

Path once trodden

Collective acceleration of ions by electron beam

Ions left out, while electrons
shoot backward

- **laser** electron acceleration
(1979)
- **laser** ion acceleration of
limited ion mass
(2009)

The electric field is

$$\epsilon = \frac{\phi_0}{v_{0f}} \cdot \frac{5}{36} \left(\frac{6}{\sqrt{3}} - \frac{z}{v_{0f}} \right),$$

where the conservation of energy was used as a boundary condition, i.e.,

$$U^{1/2} + \psi = 0 \quad \text{at} \quad \zeta = 0.$$

The maximum ion energy can now be obtained by setting $n_i = 0$, i.e.,

$$E_{max} = 6q\phi_0 \quad \text{at} \quad \zeta = 6/\sqrt{3}.$$

In the experiment the diode voltage was 0.8 MV and the ions were doubly ionized helium,⁶ thus the maximum ion energy predicted by theory is

$$E_{max} = 9.6 \text{ MeV}.$$

The experimental result⁶ for the maximum helium ion energy was 9.6 MeV and therefore is in good agreement with the theory.

The ion number as a function of energy is calculated to be

$$N_i(E_i) = \frac{n_0 A}{\beta} \left[\left(\frac{6}{5} \right)^{1/2} - \left(\frac{E_i}{5q\phi_0} \right)^{1/2} \right]^6, \quad (15)$$

where

$$n_0 A = \frac{16}{5} \frac{J_0 A}{e} \left(\frac{2m}{e\phi_0} \right)^{1/2},$$

$$\beta = (\frac{6}{5})^{1/2} (1/v_{0f}),$$

$A = \pi r_b^2$, r_b = electron beam radius,

and

$$v_0 = (q\phi_0/M)^{1/2}.$$

Equation (15) is our main result. The natural logarithm of Eq. (15) is plotted in Fig. 2 along with the experimental

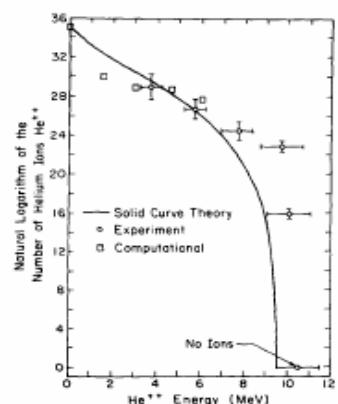

FIG. 2. Comparison between theory, experiment, and simulation, of the natural logarithm of the ion number versus energy.

data. The following experimental values were used: $J_0 = 40$ kA, $\phi_0 = 0.8$ MV, $q = 2e$ (doubly ionized helium), $t = 100$ ns and $r_b = 2.5$ cm. The agreement between Eq. (15) and the experiment⁶ is reasonable. The relation in Ref. 3 does not provide such a good fit: it has too weak a slope.

III. SCALING AND ACCESSIBILITY OF THE MODEL

In the preceding section, the analysis assumed that a self-similar state could be reached. To address the question of whether a self-similar state can be attained, a detailed analysis of the initial value problem is required. This detailed analysis should include a self-consistent treatment of the dy-
